EXPERIMENT 4

AIM: Working with Docker Network

Steps to Complete:

Step 1 - Create Network

The first step is to create a network using the CLI. This network will allow us to attach multiple containers which will be able to discover each other.

In this example, we're going to start by creating a *backend-network*. All containers attached to our backend will be on this network.

Task: Create Network

To start with we create the network with our predefined name.

```
docker network create backend-network
```

```
C:\Users\sksum>docker network create backend-netwock
e9745de19453f1fd154aee68e9da1ad77a405cbfa5f618abade18e3c40dc9963

C:\Users\sksum>
```

Task: Connect To Network

When we launch new containers, we can use the *--net* attribute to assign which network they should be connected to.

```
docker run -d --name=redis --net=backend-network redis
```

```
C:\Users\sksum>docker run -d --name=redis --net=backend-network redis
3f66cf337bc241d9cba8b0a35bf79675bd4b0b32a282d7780d7af0be3f8ecc08
```

In the next step we'll explore the state of the network.

Step 2 - Network Communication

Unlike using links, *docker network* behave like traditional networks where nodes can be attached/detached.

Task: Explore

The first thing you'll notice is that Docker no longer assigns environment variables or updates the hosts file of containers. Explore using the following two commands and you'll notice it no longer mentions other containers.

```
docker run --net=backend-network alpine ping -c1 redis
```

```
C:\Users\sksum>docker run --net=backend-netwock alpine ping -c1 redis
Unable to find image 'alpine:latest' locally
latest: Pulling from library/alpine

Status: Downloaded newer image for alpine:latest
```

Step 3 - Connect Two Containers

Docker supports multiple networks and containers being attached to more than one network at a time.

For example, let's create a separate network with a Node.js application that communicates with our existing Redis instance.

Task

The first task is to create a new network in the same way.

```
docker network create frontend-network
```

```
C:\Users\sksum>docker network create frontend-network
dcf72346f72f503c457dc0b9e99ecbb86c5bb6c99070300aad0439ef76af95f7

C:\Users\sksum>
```

When using the *connect* command it is possible to attach existing containers to the network.

```
docker network connect frontend-network redis
```

```
C:\Users\sksum>docker network connect frontend-network redis

C:\Users\sksum>
```

When we launch the web server, given it's attached to the same network it will be able to communicate with our Redis instance.

```
docker run -d -p 3000:3000 --net=frontend-network katacoda/redis-node-docker-example
```

```
C:\Users\sksum>docker run -d -p 3000:3000 --net=frontend-network katacoda/redis-node-docker-example
Unable to find image 'katacoda/redis-node-docker-example:latest' locally
latest: Pulling from katacoda/redis-node-docker-example
Image docker.io/katacoda/redis-node-docker-example:latest uses outdated schema1 manifest format. Please
upgrade to a schema2 image for better future compatibility. More information at https://docs.docker.com/

cab3d75effa3a83b79548981322d0430dca14e6ea6f61dc409c792840b110ada
```

Step 4 - Create Aliases

Links are still supported when using *docker network* and provide a way to define an Alias to the container name. This will give the container an extra DNS entry name and way to be discovered. When using --link the embedded DNS will guarantee that localised lookup result only on that container where the --link is used.

The other approach is to provide an alias when connecting a container to a network.

Connect Container with Alias

The following command will connect our Redis instance to the frontend-network with the alias of *db*.

```
docker network create frontend-network2
```

```
C:\Users\sksum>docker network create frontend-network2
5edc0aeb666b309a4451bc6fa5e9c1dc2af1907bd5ded8078b56088e603aede4
```

```
docker network connect --alias db frontend-network2 redis
```

```
C:\Users\sksum>docker network connect --alias db frontend-network2 redis
```

When containers attempt to access a service via the name db, they will be given the IP address of our Redis container.

```
docker run --net=frontend-network2 alpine ping -c1 db
```

```
PING db (172.20.0.2): 56 data bytes
64 bytes from 172.20.0.2: seq=0 ttl=64 time=0.903 ms

--- db ping statistics ---
1 packets transmitted, 1 packets received, 0% packet loss
round-trip min/avg/max = 0.903/0.903/0.903 ms
PS C:\Users\manya\OneDrive\Desktop\ACO>
```

Step 5 - Disconnect Containers

With our networks created, we can use the CLI to explore the details.

The following command will list all the networks on our host.

```
docker network lszz
```

```
C:\Users\sksum>docker network lszz

Usage:  docker network COMMAND

Manage networks

Commands:
  connect     Connect a container to a network
  create      Create a network
  disconnect  Disconnect a container from a network
  inspect     Display detailed information on one or more networks
  ls          List networks
  prune       Remove all unused networks
  rm          Remove one or more networks

Run 'docker network COMMAND --help' for more information on a command.

C:\Users\sksum>^S
```

We can then explore the network to see which containers are attached and their IP addresses.

```
docker network inspect frontend-network
```

```
C:\Users\sksum>docker network inspect frontend-network
[
    {
